

## Hyper-targeting in Digital Political Campaigns

Hyper-targeting is a marketing strategy that uses data to identify the interests of a specific individual or very small group of like-minded individuals and influence their thoughts or actions. In political campaigns, digital hyper-targeting allows candidates to send personalized political advertisements to voters based on demographic data, browsing history, and social media activity. This practice can reinforce echo chambers, as voters are only exposed to advertisements designed to trigger their specific biases. Understanding digital hyper-targeting is a critical component of modern media literacy, as it helps voters identify how their data is being used to manipulate political opinions. By recognizing these highly tailored advertisements, citizens can critically evaluate the sources of political information and maintain independent political choices.
